

## ASSESEMENT TOOL-8

ANTONY MAGRIN J(192572103)

### 1. Online Shopping Platform – Normalize to 3NF

#### Given Relation

The online shopping platform stores:

Order(OrderID, CustID, CustName, ProdID, ProdName, Qty, Price)

#### Given Table

| OrderID | CustID | CustName | ProdID | ProdName | Qty | Price |
|---------|--------|----------|--------|----------|-----|-------|
| O101    | C01    | Asha     | P01    | Laptop   | 1   | 50000 |
| O101    | C01    | Asha     | P02    | Mouse    | 2   | 800   |
| O102    | C02    | Rahul    | P01    | Laptop   | 1   | 50000 |

The same customer and product information is repeated.

#### Step 1: Identify Functional Dependencies

| No. | Functional Dependency                | Meaning                               |
|-----|--------------------------------------|---------------------------------------|
| 1   | OrderID $\rightarrow$ CustID         | Order determines customer             |
| 2   | CustID $\rightarrow$ CustName        | Customer ID determines customer name  |
| 3   | ProdID $\rightarrow$ ProdName, Price | Product ID determines product details |
| 4   | (OrderID, ProdID) $\rightarrow$ Qty  | Order + Product determines quantity   |

#### Step 2: Find Candidate Key

One order can contain many products.

Therefore, OrderID alone cannot uniquely identify a row.

ProdID alone also cannot uniquely identify a row.

Hence:

Candidate Key = (OrderID, ProdID)

### **Step 3: Convert to 1NF**

A relation is in **1NF** if:

- All values are atomic.
- There are no repeating groups.
- Each cell contains a single value.

The given table contains atomic values.

Therefore:

The relation is in 1NF.

### **Step 4: Convert to 2NF**

A relation is in 2NF if:

1. It is already in 1NF.
2. There is no partial dependency.

The candidate key is:

(OrderID, ProdID)

But:

OrderID  $\rightarrow$  CustID

and:

ProdID  $\rightarrow$  ProdName, Price

These attributes depend only on part of the composite key.

Therefore, the relation violates 2NF.

## Decompose into 2NF

### Order Table

| OrderID | CustID | CustName |
|---------|--------|----------|
| O101    | C01    | Asha     |
| O102    | C02    | Rahul    |

### Product Table

| ProdID | ProdName | Price |
|--------|----------|-------|
| P01    | Laptop   | 50000 |
| P02    | Mouse    | 800   |

### OrderItem Table

| OrderID | ProdID | Qty |
|---------|--------|-----|
| O101    | P01    | 1   |
| O101    | P02    | 2   |
| O102    | P01    | 1   |

## Step 5: Convert to 3NF

Now consider the Order table:

| OrderID | CustID | CustName |
|---------|--------|----------|
| O101    | C01    | Asha     |
| O102    | C02    | Rahul    |

Functional dependencies:

OrderID  $\rightarrow$  CustID

CustID  $\rightarrow$  CustName

Therefore:

$\text{OrderID} \rightarrow \text{CustID} \rightarrow \text{CustName}$

This is a transitive dependency.

Therefore, it violates 3NF.

### **Remove the Transitive Dependency**

#### **Customer Table**

| <b>CustID</b> | <b>CustName</b> |
|---------------|-----------------|
| C01           | Asha            |
| C02           | Rahul           |

#### **Order Table**

| <b>OrderID</b> | <b>CustID</b> |
|----------------|---------------|
| O101           | C01           |
| O102           | C02           |

#### **Product Table**

| <b>ProdID</b> | <b>ProdName</b> | <b>Price</b> |
|---------------|-----------------|--------------|
| P01           | Laptop          | 50000        |
| P02           | Mouse           | 800          |

#### **OrderItem Table**

| <b>OrderID</b> | <b>ProdID</b> | <b>Qty</b> |
|----------------|---------------|------------|
| O101           | P01           | 1          |
| O101           | P02           | 2          |
| O102           | P01           | 1          |

### Final 3NF Design

| Table                            | Primary Key      |
|----------------------------------|------------------|
| Customer(CustID, CustName)       | CustID           |
| Order(OrderID, CustID)           | OrderID          |
| Product(ProdID, ProdName, Price) | ProdID           |
| OrderItem(OrderID, ProdID, Qty)  | OrderID + ProdID |

#### Why this is in 3NF

- Customer details are stored only once.
- Product details are stored only once.
- No partial dependency remains.
- No transitive dependency remains.
- Data redundancy is reduced.

#### Anomalies Removed

**Insertion anomaly:** A new customer or product can be inserted independently.

**Update anomaly:** Customer name needs to be changed only once.

**Deletion anomaly:** Deleting an order does not delete customer information.

#### Conclusion

The original Order relation is normalized from 1NF  $\rightarrow$  2NF  $\rightarrow$  3NF by removing partial and transitive dependencies. The final design contains Customer, Order, Product, and OrderItem tables.

## 2. Hospital Patient System – Normalize to BCNF

Given Relation

Patient(PID, PName, DocID, DocName, Specialization, WardNo, WardName)

### Given Table

| PID | PName | DocID | DocName   | Specialization | WardNo | WardName |
|-----|-------|-------|-----------|----------------|--------|----------|
| P01 | Arun  | D01   | Dr. Ravi  | Cardiology     | W01    | General  |
| P02 | Priya | D01   | Dr. Ravi  | Cardiology     | W02    | ICU      |
| P03 | Kumar | D02   | Dr. Meena | Neurology      | W01    | General  |

### Step 1: Functional Dependencies

| No. | Functional Dependency                       |
|-----|---------------------------------------------|
| 1   | PID $\rightarrow$ PName, DocID, WardNo      |
| 2   | DocID $\rightarrow$ DocName, Specialization |
| 3   | WardNo $\rightarrow$ WardName               |

### Candidate Key

PID

because PID uniquely identifies a patient.

### Step 2: Identify Anomalies

#### Update Anomaly

If Dr. Ravi's specialization changes, it must be updated in every patient record associated with Dr. Ravi.

#### Insertion Anomaly

A new doctor cannot be stored unless a patient is assigned to that doctor.

#### Deletion Anomaly

If the last patient assigned to a doctor is deleted, the doctor's information may also be lost.

### **Step 3: 1NF**

All values are atomic.

Therefore:

Patient is in 1NF.

### **Step 4: 2NF**

The candidate key is a single attribute PID.

Therefore, partial dependency cannot occur.

Patient is in 2NF.

### **Step 5: 3NF**

We have:

$PID \rightarrow DocID$

$DocID \rightarrow DocName, Specialization$

Therefore:

$PID \rightarrow DocID \rightarrow DocName, Specialization$

This is a transitive dependency.

Also:

$PID \rightarrow WardNo$

$WardNo \rightarrow WardName$

Therefore:

$PID \rightarrow WardNo \rightarrow WardName$

So the original relation is not in 3NF.

### **Step 6: BCNF**

BCNF requires:

For every functional dependency  $X \rightarrow Y$ , X must be a superkey.

But:

$\text{DocID} \rightarrow \text{DocName, Specialization}$

Here DocID is not a superkey of the original relation.

Also:

$\text{WardNo} \rightarrow \text{WardName}$

Here WardNo is not a superkey.

Therefore, the original relation violates BCNF.

### Step 7: Decomposition

#### Patient Table

| PID | PName | DocID | WardNo |
|-----|-------|-------|--------|
| P01 | Arun  | D01   | W01    |
| P02 | Priya | D01   | W02    |
| P03 | Kumar | D02   | W01    |

#### Doctor Table

| DocID | DocName   | Specialization |
|-------|-----------|----------------|
| D01   | Dr. Ravi  | Cardiology     |
| D02   | Dr. Meena | Neurology      |

#### Ward Table

| WardNo | WardName |
|--------|----------|
| W01    | General  |
| W02    | ICU      |

### Final BCNF Design

| Relation                               | Primary Key |
|----------------------------------------|-------------|
| Patient(PID, PName, DocID, WardNo)     | PID         |
| Doctor(DocID, DocName, Specialization) | DocID       |
| Ward(WardNo, WardName)                 | WardNo      |

### BCNF Verification

- In Patient:  $PID \rightarrow PName, DocID, WardNo$ ; PID is the key.
- In Doctor:  $DocID \rightarrow DocName, Specialization$ ; DocID is the key.
- In Ward:  $WardNo \rightarrow WardName$ ; WardNo is the key.

Therefore, every determinant is a superkey.

### Conclusion

The hospital relation is decomposed into Patient, Doctor and Ward tables and normalized up to BCNF, eliminating redundancy and insertion, deletion and update anomalies.

## 3. University Enrollment – 2NF Decomposition

### Given Relation

Enrollment(SID, SName, CourseID, CourseName, Faculty, Grade)

### Given Table

| SID | SName | CourseID | CourseName | Faculty   | Grade |
|-----|-------|----------|------------|-----------|-------|
| S01 | Asha  | C01      | DBMS       | Dr. Kumar | A     |
| S01 | Asha  | C02      | OS         | Dr. Ravi  | B     |
| S02 | Rahul | C01      | DBMS       | Dr. Kumar | A     |

### Step 1: Functional Dependencies

| No. | Functional Dependency                      |
|-----|--------------------------------------------|
| 1   | $SID \rightarrow SName$                    |
| 2   | $CourseID \rightarrow CourseName, Faculty$ |
| 3   | $(SID, CourseID) \rightarrow Grade$        |

### Step 2: Candidate Key

A student can take multiple courses.

A course can have multiple students.

Therefore:

Candidate Key = (SID, CourseID)

### Step 3: 1NF

All values are atomic.

Therefore, the relation is in **1NF**.

### Step 4: Check 2NF

Candidate key:

(SID, CourseID)

But:

$SID \rightarrow SName$

So SName depends only on SID.

Also:

$CourseID \rightarrow CourseName, Faculty$

So CourseName and Faculty depend only on CourseID.

These are partial dependencies.

Therefore, the original relation is not in 2NF.

### Step 5: Decompose into 2NF

#### Student Table

| SID | SName |
|-----|-------|
| S01 | Asha  |
| S02 | Rahul |

#### Course Table

| CourseID | CourseName | Faculty   |
|----------|------------|-----------|
| C01      | DBMS       | Dr. Kumar |
| C02      | OS         | Dr. Ravi  |

#### Enrollment Table

| SID | CourseID | Grade |
|-----|----------|-------|
| S01 | C01      | A     |
| S01 | C02      | B     |
| S02 | C01      | A     |

### 2NF Verification

#### Student

$SID \rightarrow SName$

#### Course

$CourseID \rightarrow CourseName, Faculty$

## Enrollment

$(\text{SID}, \text{CourseID}) \rightarrow \text{Grade}$

Now there is no partial dependency.

## Final 2NF Design

| Relation                              | Primary Key    |
|---------------------------------------|----------------|
| Student(SID, SName)                   | SID            |
| Course(CourseID, CourseName, Faculty) | CourseID       |
| Enrollment(SID, CourseID, Grade)      | SID + CourseID |

## Conclusion

The original Enrollment relation is decomposed into Student, Course and Enrollment tables to remove partial dependencies and achieve 2NF.

## 4. Airline Booking – Normalize to BCNF

### Given Relation

**Booking(FlightNo, PassID, PassName, Seat, DeptCity, ArrCity, Date)**

### Given Table

| FlightNo | PassID | PassName | Seat | DeptCity | ArrCity | Date     |
|----------|--------|----------|------|----------|---------|----------|
| F101     | P01    | Asha     | 12A  | Chennai  | Delhi   | 12-08-26 |
| F101     | P02    | Rahul    | 12B  | Chennai  | Delhi   | 12-08-26 |
| F102     | P01    | Asha     | 10A  | Chennai  | Mumbai  | 13-08-26 |

### Functional Dependencies

| No. | Functional Dependency                                                   |
|-----|-------------------------------------------------------------------------|
| 1   | $\text{PassID} \rightarrow \text{PassName}$                             |
| 2   | $\text{FlightNo} \rightarrow \text{DeptCity}, \text{ArrCity}$           |
| 3   | $(\text{FlightNo}, \text{PassID}) \rightarrow \text{Seat}, \text{Date}$ |

## Candidate Key

(FlightNo, PassID)

## 1NF

All values are atomic.

Therefore, it is in 1NF.

## 2NF

The key is (FlightNo, PassID).

But:

PassID  $\rightarrow$  PassName

and:

FlightNo  $\rightarrow$  DeptCity, ArrCity

These are partial dependencies.

Therefore, the relation violates 2NF.

## Decomposition

### Passenger Table

| PassID | PassName |
|--------|----------|
| P01    | Asha     |
| P02    | Rahul    |

### Flight Table

| FlightNo | DeptCity | ArrCity |
|----------|----------|---------|
| F101     | Chennai  | Delhi   |
| F102     | Chennai  | Mumbai  |

## Booking Table

| FlightNo | PassID | Seat | Date     |
|----------|--------|------|----------|
| F101     | P01    | 12A  | 12-08-26 |
| F101     | P02    | 12B  | 12-08-26 |
| F102     | P01    | 10A  | 13-08-26 |

## BCNF Verification

### Passenger

$\text{PassID} \rightarrow \text{PassName}$

PassID is the key.

### Flight

$\text{FlightNo} \rightarrow \text{DeptCity}, \text{ArrCity}$

FlightNo is the key.

### Booking

$(\text{FlightNo}, \text{PassID}) \rightarrow \text{Seat}, \text{Date}$

The composite determinant is the key.

Therefore, all relations satisfy BCNF.

## Conclusion

The airline booking relation is decomposed into Passenger, Flight and Booking and normalized up to BCNF.

## 5. HR System – Normalize to 3NF

### Given Relation

Employee(EmpID, EmpName, DeptID, DeptName, ManagerID, ManagerName, Salary)

### Given Table

| EmpID | EmpName | DeptID | DeptName | ManagerID | ManagerName | Salary |
|-------|---------|--------|----------|-----------|-------------|--------|
| E01   | Asha    | D01    | CSE      | M01       | Kumar       | 50000  |
| E02   | Rahul   | D01    | CSE      | M01       | Kumar       | 45000  |
| E03   | Priya   | D02    | ECE      | M02       | Ravi        | 55000  |

### Functional Dependencies

| No. | Functional Dependency                                  |
|-----|--------------------------------------------------------|
| 1   | EmpID $\rightarrow$ EmpName, DeptID, ManagerID, Salary |
| 2   | DeptID $\rightarrow$ DeptName, ManagerID               |
| 3   | ManagerID $\rightarrow$ ManagerName                    |

### Candidate Key

EmpID

### Transitive Dependencies

We have:

EmpID  $\rightarrow$  DeptID

DeptID  $\rightarrow$  DeptName

Therefore:

EmpID  $\rightarrow$  DeptID  $\rightarrow$  DeptName

Similarly:

$\text{EmpID} \rightarrow \text{ManagerID}$

$\text{ManagerID} \rightarrow \text{ManagerName}$

Therefore:

$\text{EmpID} \rightarrow \text{ManagerID} \rightarrow \text{ManagerName}$

These are transitive dependencies.

## Decomposition

### Employee Table

| EmpID | EmpName | DeptID | ManagerID | Salary |
|-------|---------|--------|-----------|--------|
| E01   | Asha    | D01    | M01       | 50000  |
| E02   | Rahul   | D01    | M01       | 45000  |
| E03   | Priya   | D02    | M02       | 55000  |

### Department Table

| DeptID | DeptName | ManagerID |
|--------|----------|-----------|
| D01    | CSE      | M01       |
| D02    | ECE      | M02       |

### Manager Table

| ManagerID | ManagerName |
|-----------|-------------|
| M01       | Kumar       |
| M02       | Ravi        |

## 3NF Verification

- Employee:  $\text{EmpID} \rightarrow \text{EmpName}, \text{DeptID}, \text{ManagerID}, \text{Salary}$
- Department:  $\text{DeptID} \rightarrow \text{DeptName}, \text{ManagerID}$
- Manager:  $\text{ManagerID} \rightarrow \text{ManagerName}$

The transitive dependencies have been removed from Employee.

### Conclusion

The HR schema is normalized to **3NF** by separating Employee, Department and Manager information.

## 6. Library – Identify MVDs and Decompose to 4NF

### Given Relation

Library(MemberID, MemberName, BookID, Title, Author, Genre, BorrowDate)

### Given Table

| MemberID | MemberName | BookID | Title | Author       | Genre     | BorrowDate |
|----------|------------|--------|-------|--------------|-----------|------------|
| M01      | Asha       | B01    | DBMS  | Korth        | Technical | 10-08-26   |
| M01      | Asha       | B02    | OS    | Silberschatz | Technical | 11-08-26   |
| M01      | Asha       | B03    | Novel | Author A     | Fiction   | 12-08-26   |

### Functional Dependencies

MemberID  $\rightarrow$  MemberName

BookID  $\rightarrow$  Title, Author

### Multivalued Dependencies

Assume a member can have multiple independent books and genres.

Therefore:

MemberID  $\twoheadrightarrow$  BookID

and

MemberID  $\twoheadrightarrow$  Genre

These are **multivalued dependencies (MVDs)**.

### 4NF Rule

A relation is in 4NF if:

For every non-trivial MVD  $X \twoheadrightarrow Y$ ,  $X$  must be a superkey.

Here MemberID is not a superkey for the whole relation.

Therefore, the relation violates **4NF**.

### Decomposition

#### Member Table

| MemberID | MemberName |
|----------|------------|
| M01      | Asha       |

#### Book Table

| BookID | Title | Author       |
|--------|-------|--------------|
| B01    | DBMS  | Korth        |
| B02    | OS    | Silberschatz |
| B03    | Novel | Author A     |

#### MemberBook Table

| MemberID | BookID | BorrowDate |
|----------|--------|------------|
| M01      | B01    | 10-08-26   |
| M01      | B02    | 11-08-26   |
| M01      | B03    | 12-08-26   |

### MemberGenre Table

| MemberID | Genre     |
|----------|-----------|
| M01      | Technical |
| M01      | Fiction   |

### Conclusion

The independent multivalued dependencies are separated into different relations. Therefore, the database is decomposed into relations satisfying 4NF, reducing redundancy caused by independent multivalued facts.

## 7. Telecom Billing – Candidate Keys, Primary Key and FDs

### Given Relation

Billing(BillID, CustomerID, CustomerName, PhoneNo, PlanID, PlanName, CallID, CallDuration, Amount)

### Given Table

| BillID | CustomerID | CustomerName | PhoneNo | PlanID | PlanName | CallID | CallDuration | Amount |
|--------|------------|--------------|---------|--------|----------|--------|--------------|--------|
| B01    | C01        | Asha         | 98765   | PL01   | Basic    | CL01   | 10           | 100    |
| B01    | C01        | Asha         | 98765   | PL01   | Basic    | CL02   | 20           | 200    |
| B02    | C02        | Rahul        | 91234   | PL02   | Premium  | CL03   | 15           | 180    |

## Functional Dependencies

| No. | FD                                               |
|-----|--------------------------------------------------|
| 1   | BillID $\rightarrow$ CustomerID, PhoneNo, PlanID |
| 2   | CustomerID $\rightarrow$ CustomerName            |
| 3   | PlanID $\rightarrow$ PlanName                    |
| 4   | CallID $\rightarrow$ CallDuration                |
| 5   | (BillID, CallID) $\rightarrow$ Amount            |

## Candidate Keys

Depending on the business rule:

- BillID identifies a bill.
- (BillID, CallID) identifies a billing detail/call record.

For the complete bill-detail relation, a suitable candidate key is:

(BillID, CallID)

## Primary Key

If the system treats each bill as uniquely identified by BillID, then:

Primary Key = BillID

For individual call details:

Composite Key = (BillID, CallID)

## Partial Dependencies

If (BillID, CallID) is the key:

BillID  $\rightarrow$  CustomerID, PhoneNo, PlanID

These depend only on BillID, which is part of the composite key.

Therefore, partial dependencies exist.

## Transitive Dependencies

BillID  $\rightarrow$  CustomerID

CustomerID  $\rightarrow$  CustomerName

Therefore:

BillID  $\rightarrow$  CustomerID  $\rightarrow$  CustomerName

Similarly:

BillID  $\rightarrow$  PlanID

PlanID  $\rightarrow$  PlanName

Therefore:

BillID  $\rightarrow$  PlanID  $\rightarrow$  PlanName

## Possible Normalized Design

### Customer

| CustomerID | CustomerName |
|------------|--------------|
| C01        | Asha         |
| C02        | Rahul        |

## Plan

| PlanID | PlanName |
|--------|----------|
| PL01   | Basic    |
| PL02   | Premium  |

## Bill

| BillID | CustomerID | PhoneNo | PlanID |
|--------|------------|---------|--------|
| B01    | C01        | 98765   | PL01   |
| B02    | C02        | 91234   | PL02   |

## Call

| CallID | CallDuration |
|--------|--------------|
| CL01   | 10           |
| CL02   | 20           |
| CL03   | 15           |

## BillCall

| BillID | CallID | Amount |
|--------|--------|--------|
| B01    | CL01   | 100    |
| B01    | CL02   | 200    |
| B02    | CL03   | 180    |

## Conclusion

Before normalization, the important tasks are to identify candidate keys, primary keys, functional dependencies, partial dependencies and transitive dependencies. These dependencies guide further normalization.

## 8. Retail Inventory – Complete Normalization

### Given Relation

**Product(PID, PName, SupplierID, SupplierName, Category, Price, Warehouse)**

### Given Table

| PID | PName    | SupplierID | SupplierName | Category    | Price | Warehouse |
|-----|----------|------------|--------------|-------------|-------|-----------|
| P01 | Laptop   | S01        | ABC Ltd      | Electronics | 50000 | W01       |
| P02 | Mouse    | S01        | ABC Ltd      | Electronics | 800   | W01       |
| P03 | Keyboard | S02        | XYZ Ltd      | Electronics | 1500  | W02       |

### Functional Dependencies

| No. | FD                                                              |
|-----|-----------------------------------------------------------------|
| 1   | PID $\rightarrow$ PName, SupplierID, Category, Price, Warehouse |
| 2   | SupplierID $\rightarrow$ SupplierName                           |

### Candidate Key

PID

**1NF**

All values are atomic.

Therefore:

Product is in 1NF.

## 2NF

The candidate key consists of only one attribute:

PID

Therefore, partial dependency is impossible.

So:

Product is in 2NF.

## 3NF

We have:

$PID \rightarrow SupplierID$

and:

$SupplierID \rightarrow SupplierName$

Therefore:

$PID \rightarrow SupplierID \rightarrow SupplierName$

This is a transitive dependency.

Therefore, the original relation violates **3NF**.

## Decomposition

### Product Table

| PID | PName    | SupplierID | Category    | Price | Warehouse |
|-----|----------|------------|-------------|-------|-----------|
| P01 | Laptop   | S01        | Electronics | 50000 | W01       |
| P02 | Mouse    | S01        | Electronics | 800   | W01       |
| P03 | Keyboard | S02        | Electronics | 1500  | W02       |

### Supplier Table

| SupplierID | SupplierName |
|------------|--------------|
| S01        | ABC Ltd      |
| S02        | XYZ Ltd      |

### BCNF Check

#### Product

$PID \rightarrow PName, SupplierID, Category, Price, Warehouse$

PID is a superkey.

#### Supplier

$SupplierID \rightarrow SupplierName$

SupplierID is a superkey.

Therefore, the resulting relations satisfy BCNF under the given dependencies.

### Conclusion

The Product relation is normalized through:

$1NF \rightarrow 2NF \rightarrow 3NF$ , and the resulting relations also satisfy BCNF under the stated dependencies.

## 9. School ERP – Normalize to BCNF

### Given Relation

School(StudentID, StudentName, ClassID, ClassName, TeacherID, TeacherName, SubjectID, SubjectName, Grade)

### Given Table

| StudentID | StudentName | ClassID | ClassName | TeacherID | TeacherName | SubjectID | SubjectName | Grade |
|-----------|-------------|---------|-----------|-----------|-------------|-----------|-------------|-------|
| S01       | Asha        | C01     | II CSE    | T01       | Kumar       | SUB01     | DBMS        | A     |
| S01       | Asha        | C01     | II CSE    | T01       | Kumar       | SUB02     | OS          | B     |
| S02       | Rahul       | C01     | II CSE    | T01       | Kumar       | SUB01     | DBMS        | A     |

### Functional Dependencies

| No. | Functional Dependency                        |
|-----|----------------------------------------------|
| 1   | StudentID $\rightarrow$ StudentName, ClassID |
| 2   | ClassID $\rightarrow$ ClassName, TeacherID   |
| 3   | TeacherID $\rightarrow$ TeacherName          |
| 4   | SubjectID $\rightarrow$ SubjectName          |
| 5   | (StudentID, SubjectID) $\rightarrow$ Grade   |

### Candidate Key

A student can study multiple subjects.

Therefore:

**Candidate Key = (StudentID, SubjectID)**

### 1NF

All values are atomic.

Therefore, the relation is in 1NF.

## 2NF

$\text{StudentID} \rightarrow \text{StudentName}, \text{ClassID}$

and:

$\text{SubjectID} \rightarrow \text{SubjectName}$

These depend on only part of the composite key.

Therefore, the relation violates 2NF.

## 3NF

We have:

$\text{StudentID} \rightarrow \text{ClassID}$

$\text{ClassID} \rightarrow \text{ClassName}, \text{TeacherID}$

Therefore:

$\text{StudentID} \rightarrow \text{ClassID} \rightarrow \text{ClassName}, \text{TeacherID}$

Also:

$\text{TeacherID} \rightarrow \text{TeacherName}$

Therefore:

$\text{StudentID} \rightarrow \text{ClassID} \rightarrow \text{TeacherID} \rightarrow \text{TeacherName}$

These are transitive dependencies.

## BCNF Decomposition

### Student Table

| StudentID | StudentName | ClassID |
|-----------|-------------|---------|
| S01       | Asha        | C01     |
| S02       | Rahul       | C01     |

### Class Table

| ClassID | ClassName | TeacherID |
|---------|-----------|-----------|
| C01     | II CSE    | T01       |

### Teacher Table

| TeacherID | TeacherName |
|-----------|-------------|
| T01       | Kumar       |

### Subject Table

| SubjectID | SubjectName |
|-----------|-------------|
| SUB01     | DBMS        |
| SUB02     | OS          |

### Enrollment Table

| StudentID | SubjectID | Grade |
|-----------|-----------|-------|
| S01       | SUB01     | A     |
| S01       | SUB02     | B     |
| S02       | SUB01     | A     |

## BCNF Verification

| Relation   | Functional Dependency                           | Determinant      |
|------------|-------------------------------------------------|------------------|
| Student    | StudentID $\rightarrow$ StudentName,<br>ClassID | StudentID is key |
| Class      | ClassID $\rightarrow$ ClassName, TeacherID      | ClassID is key   |
| Teacher    | TeacherID $\rightarrow$ TeacherName             | TeacherID is key |
| Subject    | SubjectID $\rightarrow$ SubjectName             | SubjectID is key |
| Enrollment | (StudentID, SubjectID) $\rightarrow$ Grade      | Composite key    |

Every determinant is a superkey.

Therefore, the design satisfies BCNF.

## Conclusion

The poorly normalized School ERP is decomposed into Student, Class, Teacher, Subject and Enrollment tables and normalized up to BCNF.

## 10. Movie Streaming Platform – 5NF

### Given Relation

Consider:

Streaming(UserID, MovieID, ActorID)

### Example Table

| UserID | MovieID | ActorID |
|--------|---------|---------|
| U01    | M01     | A01     |
| U01    | M01     | A02     |
| U02    | M01     | A01     |
| U02    | M02     | A03     |

Assume the system maintains three independent relationships:

1. User watches Movie.
2. Actor appears in Movie.
3. User has a relationship with Actor.

### Step 1: Identify Join Dependency

The original relation:

Streaming(UserID, MovieID, ActorID)

can be represented using three projections:

#### UserMovie

| UserID | MovieID |
|--------|---------|
| U01    | M01     |
| U02    | M01     |
| U02    | M02     |

#### MovieActor

| MovieID | ActorID |
|---------|---------|
| M01     | A01     |
| M01     | A02     |
| M02     | A03     |

#### UserActor

| UserID | ActorID |
|--------|---------|
| U01    | A01     |
| U01    | A02     |
| U02    | A01     |
| U02    | A03     |

The join dependency is:

Streaming = UserMovie  $\bowtie$  MovieActor  $\bowtie$  UserActor

## Step 2: Why 5NF?

A relation is in 5NF when every non-trivial join dependency is implied by candidate keys.

The original relation combines three independent relationships.

This may create unnecessary combinations and redundancy.

Therefore, it should be decomposed.

## Step 3: 5NF Decomposition

### UserMovie Table

| UserID | MovieID |
|--------|---------|
| U01    | M01     |
| U02    | M01     |
| U02    | M02     |

### MovieActor Table

| MovieID | ActorID |
|---------|---------|
| M01     | A01     |
| M01     | A02     |
| M02     | A03     |

### UserActor Table

| UserID | ActorID |
|--------|---------|
| U01    | A01     |
| U01    | A02     |
| U02    | A01     |
| U02    | A03     |

#### **Step 4: Lossless Join**

The original relation can be reconstructed as:

UserMovie  $\bowtie$  MovieActor  $\bowtie$  UserActor

Therefore, when the assumed join dependency is valid, the decomposition is lossless.

The decomposition separates:

- User–Movie relationship
- Movie–Actor relationship
- User–Actor relationship

#### **Step 5: Advantages**

1. Reduces redundancy.
2. Avoids unnecessary combinations.
3. Simplifies insertion.
4. Simplifies deletion.
5. Maintains independent relationships.
6. Provides a lossless decomposition under the stated join dependency.

#### **Conclusion**

The Movie Streaming relation contains a join dependency and is decomposed into UserMovie, MovieActor and UserActor. The original relation can be reconstructed using natural joins, making the decomposition lossless and satisfying 5NF under the stated business rules.
